

# NYC Building Energy Efficiency

Steven Litvack-Winkler (Data Scientist)

# Problem Statement

Buildings are a major source of energy consumption in New York. Given New York's goals to greatly reduce greenhouse gas emissions, what aspects are associated with high or low energy efficiency?

New York Energy Consumption by End-Use Sector, 2019

Source: Energy Information Administration, State Energy Data System

# Data Source

- ENERGY STAR Portfolio Manager
  - Private buildings > 25,000 square feet
- NYC Open Data aggregates and publishes this information ([here](#))

# Data Overview

- 28,067 total properties with 16,894 in multifamily housing category
- Identification columns
  - Name, id
- Property information
  - Type, square footage, year built
- Location columns
  - Address, borough, neighborhood
- Energy usage columns
  - Energy use intensity, total emissions
- Messy data with missing values, duplicates, inconsistent field values / names and outliers
  - One rehab / nursing center used  $6.4 \times 10^{10}$  kBtu of steam power in 2020, about equal to an atomic bomb or calories consumed by 10 million people in a year

# Property Type Comparison

Property Type	Total GHG Emissions	Number of Properties
Multifamily Housing	9616037.2	18702
Office	2909336.4	2338
Hospital (General Medical & Surgical)	859730.0	82
K-12 School	719067.5	1614
College/University	650218.8	301

# Monthly Electricity Consumption

## Average Year Built by Borough

## Average Total Residenital Living Units by Borough

## Average Gross Floor Square Feet by Borough

## Average Parking Square Feet by Borough

## Average Units in High Rises by Borough

## Average Number of Laundry Hookups in Units by Borough

## Average Source EUI (kBtu) per Square Foot by Borough

## Average Electricity Usage (kBtu) per Square Foot by Borough

## Average Total Emissions (kgCO<sub>2</sub>e) per Square Foot by Borough

# Model to predict energy consumption

Target - total greenhouse gas emissions intensity

## Features

- \* borough (with a one hot encoding)
- \* gross floor square footage
- \* ratio of square footage for parking
- \* year built
- \* occupancy ratio
- \* government\_subsidized\_housing flag
- \* high rise and mid rise flags

# Model to predict energy consumption

- Target - total greenhouse gas emissions intensity
- Linear regression
  - Almost all features are statistically significant but  $R^2$  is only 0.05

# Conclusions / Takeaways

- Greenhouse gas emissions are not easily explained by factors like demographics, location, and size.
- Real world data is messy and collecting / cleaning it is very time consuming.
- Choropleth maps are powerful ways to visualize geographic data.

# Future Steps

- Compare to prior years of data, study if buildings become more / less efficient over time.
- Maps at more localized levels.
- Use more powerful models to predict ghg emissions.
- Explore other publicly available data that explains more of the variance in ghg emissions.
- Understand current official websites and reports on NYC environmental building data.
